

SH6/SH8B Intersection Upgrade - Traffic Modelling Assessment

Introduction

This short technical note sets out an operational assessment of the proposed SH6/SH8B intersection upgrade.

The Regional package of Waka Kotahi NZ Transport Agency New Zealand Upgrade Programme includes a determination to build a new roundabout at the SH6/SH8B intersection, to improve road safety and accommodate future traffic growth. This technical note investigates whether a single lane roundabout will adequately cope with growth demands into the medium to long term future.

Proposed Upgrade

It is proposed to upgrade the existing priority-controlled intersection to a roundabout, to improve efficiency and road safety. Based on WSP's local knowledge of Cromwell traffic it is anticipated that a single lane roundabout will cater for traffic demands now and well into the future, while minimising any potential complexities associated with a dual lane roundabout. The assumed single lane roundabout layout is shown in Figure 1.

Figure 1: Proposed improvement to SH6/SH8B intersection

Traffic Assessment

The assessment seeks to provide information on the likely life of a single lane roundabout, given that it is proposed to ensure that the roundabout footprint can be protected to provide a dual lane roundabout in the future. Therefore, an assessment of the operation of the existing intersection layout has not been undertaken.

Operational assessments have been undertaken in both SIDRA and VISSIM - the operation of a roundabout layout can result in a higher variation in results (compared to a signal- controlled intersection) due to site factors such as approach speed, circulatory speed, visibility and vehicle composition.

Base Year Traffic Volumes

The closest NZ Transport Agency telemetry site is located on State Highway 8B between the intersections with State Highway 6 and Sargood Road. The AADT of this site, for the 9-year period between 2010 and 2019, is shown as follows in Figure 2, together with the AADT measured at the next 3 nearest sites.

Donalistics.	Year										Growth per annum		
Description	2010	2011	2012	2013	2014	2015	2016	2017	2018	2019	2010-2015	2015-2019	2010-2019

Figure 2: AADT volumes (in vehicles)

The table shows:

- Growth from 2010 to 2015 was relatively low at around 1.5% per annum at the close-by SH8B site (likely associated with the Global Financial Crisis economic slowdown)
- From 2015 to 2019, growth was significant, with an average of 13% per annum reflecting the growth in both tourism in Central Otago (and Queenstown Lakes), and the interlinked increase in population to serve the tourist market
- Overall, this generated a 9-year growth of over 6% per annum on this count site

Due to the impact of COVID-19, traffic counts at the intersection itself have not been possible, as they would not be fully representative of the "normal" traffic patterns. The most recent count was carried out in support of CODC Plan Change 13 by Carriageway Consulting Limited and is set out in the Transportation Assessment and subsequent Plan Change evidence presented in 2019. Although the turning count survey was not dated within the evidence it is assumed to have been undertaken in early 2019.

As a means to check the validity of this count (in terms of it being generally representative of traffic volumes in 2019), we have compared this turning count to:

- A 2016 count in support of the Wooing Tree development (CODC Plan Change 12) carried out by WSP (then Opus)
- The two-way link flows at the NZ Transport Agency telemetry site 08B00002 on SH8B (close to the SH6/SH8B intersection), for three weeks in November 2019 (Tue-Thurs inclusive only)

Table 1 shows the results of this comparison, with the following conclusions:

- The 2016 and 2019 counts appear to be the same. This suggests that PC13 presented unfactored 2016 counts, rather than new counts taken in 2019 for this intersection
- Growth is significant between the 2016 count and the TMS link count in 2019, at a total of 28% in the AM peak hour and 17% in the PM peak hour. This is still, however, less than the equivalent of 13% per annum growth shown on the TMS site in Figure 2 although this figure does show that the greatest increase in traffic volumes was reported between 2015 and 2016

Consequently, we have factored up the original 2016 turning counts by the factors set out in Table 1, to establish a synthesised 2019 set of turning counts for the base year assessment.

Future Year Volumes

The assessment of the proposed intersection upgrade has been carried out at 2039 and 2049. Two growth scenarios have been used:

- "High growth" we have used the 6.3% per annum linear growth from Figure 2 for the 2010-2019 period as a high growth scenario. Despite the 2015-2019 period showing higher growth than this level, this is thought to be unsustainable in the longer term, particularly when viewed from the current conditions of the COVID-19 pandemic, which is likely to result in suppressed growth (particularly from international tourism) over the next 3-5 years
- "Low growth" we have used a 50% rate of the high growth scenario. This level of growth is still higher (around double) that of the 2010 to 2015 period, and so still represents a moderate level compared to historic forecasts

It should be noted that the current population projections from Stats NZ from 2018 to 2043, show an increase of less than 1% per annum for the Cromwell area unit – whilst this seems likely to be an underestimate given potential development activity in the area, it does show some context for the 3% per annum used above for the Low growth scenario.

An alternative method to establish likely traffic growth into the future is to consider the individual impact of proposed Plan Changes and other developments in the area (such as Wooing Tree, River Terrace and Shannon Farm). However, there is significant uncertainty over the time frames for delivery of these new residential developments, we have not used a method to determine the likely cumulative effect of development related trips on the SH6/SH8B intersection – instead preferring the consideration of global growth factors, as indicated above.

Table 2 sets out the resultant forecast turning volumes at 2039 and 2049 for the two growth scenarios. We have presented the volumes for the worst-case PM peak hour period only - and the modelling has also only been carried for this critical period.

Table 2: Forecast Turning Movements at SH6/SH8B Intersection

Total growth (f	rom 2019)	63%	127%	95%	190%		

Assessment Results

Table 3 shows the results of both SIDRA and VISSIM assessments of the following traffic volume scenarios for the proposed single lane roundabout (SIDRA output is also included in Appendix A):

- 2019 base
- 2039 low growth
- 2039 high growth
- 2049 low growth
- 2049 high growth

A number of conclusions can be drawn from the results:

- The SIDRA and VISSIM results are generally well aligned, giving confidence that the forecast operational levels in each scenario are a good representation of the likely performance
- Both low growth scenarios (2039 and 2049) show satisfactory operation of the proposed roundabout, with all movements predicted to operate with LOS A (average delay less than 10 seconds per vehicle), with all maximum queue lengths predicted to be 100m or less. This shows that the roundabout can accommodate traffic volumes comfortably up to 100% higher than the base year 2019 levels
- At 2039 high growth, the roundabout operates satisfactory, although the two SH6
 approaches are predicted to move into the LOS B performance level (10 to 20 seconds per
 vehicle), with the SIDRA results predicting LOS C for the right turn from SH6 West to SH8B.
 However, maximum queue lengths are still around 150m, on these approaches, and around
 half that level on the SH8B approach (due to comparatively low volumes passing this
 approach on the circulatory)
- At 2049 high growth, performance is poor, with overall LOS F+ predicted for the intersection as a whole in both models. Performance is particularly poor on the SH6 West approach due to a combination of a high approach volume, and high conflicting volume on the circulatory

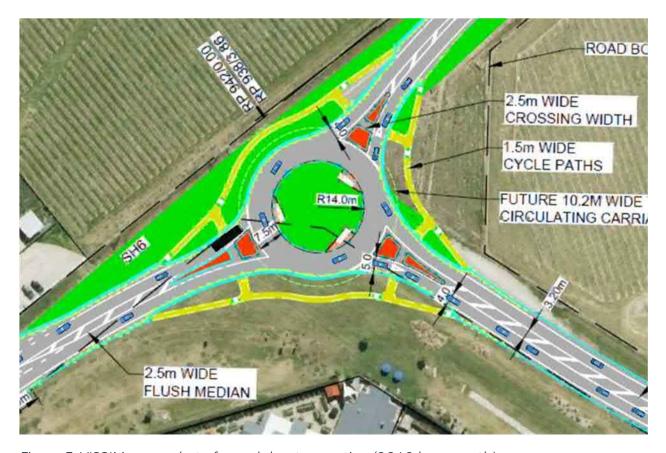

Figure 3: VISSIM screenshot of roundabout operation (2049 low growth)

In conclusion, this suggests that a total growth of around 150% on top of the base 2019 volumes can be accommodated, before the roundabout would need to be upgraded to include two-lane circulatory and approach lanes. Although this could be staged, and the SH6 West approach becomes critical first, all approaches carry significant volumes, and it is recommended that an improvement on all three arms would be required.

From this analysis, it would appear that a reasonable trigger of the second-stage improvement (to a dual-circulatory roundabout) would be once volumes are around 100% higher than the current (2019) volumes, to provide some float time for the initiation of the design and construction of the second stage. From the analysis, this is likely to be between 2035 (assuming high growth) and 2049 (assuming low growth).

Site Level of Service (LOS) Method: Delay (SIDRA). Site LOS Method is specified in the Parameter Settings dialog (Site tab).

Roundabout LOS Method: SIDRA Roundabout LOS.

Vehicle movement LOS values are based on average delay per movement.

Intersection and Approach LOS values are based on average delay for all vehicle movements.

Roundabout Capacity Model: SIDRA Standard.

SIDRA Standard Delay Model is used. Control Delay includes Geometric Delay.

Gap-Acceptance Capacity: SIDRA Standard (Akçelik M3D).

HV (%) values are calculated for All Movement Classes of All Heavy Vehicle Model Designation.

SH6/SH8B Intersection Upgrade - Traffic Modelling Assessment - Addendum

Introduction

This Addendum sets out the results of a revised assessment of the operational performance of the proposed SH6/SH8B intersection upgrade.

Since the original Technical Note was provided, the proposed layout was updated to include a 20m centre island radius, instead of the original 14m radius. This note provides a brief update to the results due to this change.

Proposed Upgrade

An indicative single lane roundabout with 20m central island layout is shown in Figure 1. This layout still allows a future upgrade to include two-lane circulatory and approach lanes when required in the longer term. It should be noted, however, that the design is still undergoing an update to allow for a potential fourth leg to be located to the North West between the SH6 approaches. As this provision is being included purely to prevent preclusion of a future fourth leg, it has not been factored into the modelling.

Similarly the approach geometry on the existing legs will be adjusted slightly from the layout below but this is not expected to have any significant impact on the modelling results.

Figure 1: Proposed improvement to SH6/SH8B intersection - 20m radius island

Traffic Assessment

An operational assessment has been undertaken in SIDRA of the revised layout, and compared with the results of the original 14m radius version, for two scenarios: The VISSIM model has not been updated at this time, but it is expected that the change in operation performance would be

similar in scale to the SIDRA analysis (given that results were similar across all scenarios in the original assessments).

Future Year Volumes

The revised assessment of the proposed intersection upgrade has been carried out at 2039 for both low and high growth scenarios, as the per the original analysis.

Assessment Results

Table 1 shows the results of the SIDRA assessments of the following traffic volume scenarios for the proposed single lane roundabout:

- 2039 low growth 14m radius centre island
- 2039 low growth 20m radius centre island
- 2039 high growth 14m radius centre island
- 2039 high growth 20m radius centre island

The results show there is a marginal improvement in operation of the roundabout, as would be expected. The predicted improvement in capacity is around 5-10% (as a comparison of the RFC values) – this is equivalent to around 2-3 years of low growth, and 1-2 years of high growth. Queue lengths and delay results also show a marginal improvement in both growth scenarios.

This demonstrates that the trigger points for upgrade to a two-lane circulatory would be slightly extended due to the increase in island diameter.

Table 1: Assessment Results (SIDRA) comparing the 14m and 20m radius island layouts options
